#### 1.1 Task

Compute DH table, direct kinematics, inverse kinematics, geometric Jacobian, analytical Jacobian by hand and cross-checking with Robotics toolbox.

#### 1.2 Robot model

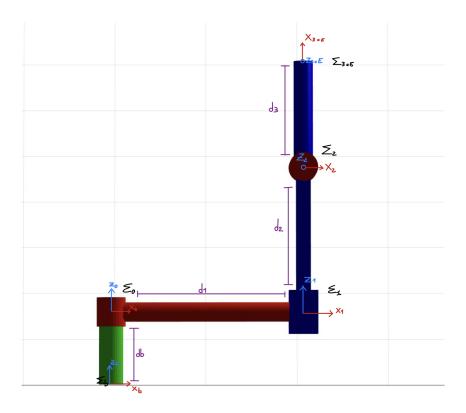

Figure 1: Robot model with frames

The d parameters representing the robot links lengths are:

- $d_0 = 0.15$
- $d_1 = 0.40$
- $d_2 = 0.30$
- $d_3 = 0.24$

#### 1.3 DH Table

	$\theta$	$\alpha$	d	a
B-0	0	0	$d_b$	0
0-1	$q_1$	0	0	$d_1$
1-2	0	$\frac{\pi}{2}$	$d_2 + q_2$	0
2-E	$\frac{\pi}{2} + q_3$	0	0	$d_3$

Table 1: DH table of the robot model

#### 1.4 Direct Kinematics

It'll follow a list of rotational matrices describing the changes of coordinates from the various frames  $\Sigma$  with respect to  $\Sigma_B$ :

$$T_0^B = \left( \begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & \mathrm{d_b} \\ 0 & 0 & 0 & 1 \end{array} \right) \qquad T_1^B = \left( \begin{array}{cccc} \cos\left(q_1\right) & -\sin\left(q_1\right) & 0 & d_1\cos\left(q_1\right) \\ \sin\left(q_1\right) & \cos\left(q_1\right) & 0 & d_1\sin\left(q_1\right) \\ 0 & 0 & 1 & \mathrm{d_b} \\ 0 & 0 & 0 & 1 \end{array} \right)$$

$$T_2^B = \begin{pmatrix} \cos(q_1) & 0 & \sin(q_1) & d_1 \cos(q_1) \\ \sin(q_1) & 0 & -\cos(q_1) & d_1 \sin(q_1) \\ 0 & 1 & 0 & d_2 + d_b + q_2 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$T_{E}^{B} = \begin{pmatrix} \cos{(q_{1})}\cos{(q_{3} + \frac{\pi}{2})} & -\cos{(q_{1})}\sin{(q_{3} + \frac{\pi}{2})} & \sin{(q_{1})} & d_{1}\cos{(q_{1})} + d_{3}\cos{(q_{1})}\cos{(q_{3} + \frac{\pi}{2})} \\ \cos{(q_{3} + \frac{\pi}{2})}\sin{(q_{1})} & -\sin{(q_{1})}\sin{(q_{3} + \frac{\pi}{2})} & -\cos{(q_{1})} & d_{1}\sin{(q_{1})} + d_{3}\cos{(q_{3} + \frac{\pi}{2})}\sin{(q_{1})} \\ \sin{(q_{3} + \frac{\pi}{2})} & \cos{(q_{3} + \frac{\pi}{2})} & 0 & d_{2} + d_{b} + q_{2} + d_{3}\sin{(q_{3} + \frac{\pi}{2})} \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

It'll now follow a list of transformation from frame to frame:

$$T_0^B = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & d_b \\ 0 & 0 & 0 & 1 \end{pmatrix} \qquad T_1^0 = \begin{pmatrix} \cos(q_1) & -\sin(q_1) & 0 & d_1\cos(q_1) \\ \sin(q_1) & \cos(q_1) & 0 & d_1\sin(q_1) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$T_{2}^{1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & d_{2} + q_{2} \\ 0 & 0 & 0 & 1 \end{pmatrix} \qquad T_{E}^{2} = \begin{pmatrix} \cos\left(q_{3} + \frac{\pi}{2}\right) & -\sin\left(q_{3} + \frac{\pi}{2}\right) & 0 & d_{3}\cos\left(q_{3} + \frac{\pi}{2}\right) \\ \sin\left(q_{3} + \frac{\pi}{2}\right) & \cos\left(q_{3} + \frac{\pi}{2}\right) & 0 & d_{3}\sin\left(q_{3} + \frac{\pi}{2}\right) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

#### 1.5 Inverse Kinematics

Given the direct kinematics after semplification:

$$p_E^B = \begin{pmatrix} \cos(q_1) & (d_1 - d_3 \sin(q_3)) \\ \sin(q_1) & (d_1 - d_3 \sin(q_3)) \\ d_2 + d_b + q_2 + d_3 \cos(q_3) \end{pmatrix} = \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

We obtain the following inverse kinematics:

$$InvKin = \begin{pmatrix} atan2(y,x) \\ -(d_2 + d_b + d_3cos(q_3sol)) + z \\ q_3sol \end{pmatrix} = \begin{pmatrix} q_1 \\ q_2 \\ q_3 \end{pmatrix}$$

Where  $q_3sol$  is the the following:

$$q_3 sol = \begin{cases} asin(-\frac{1}{d_3}(\frac{y}{\sin(q_1)} - d_1)) & if q_1 = \pi/2\\ acos(-\frac{1}{d_2}(\frac{y}{\cos(q_1)} - d_1)) & otherwise \end{cases}$$

The result was compared with the robotic toolbox one and was shown to be exactly the same.

#### 1.6 Geometric Jacobian

Following:

$$J = \begin{bmatrix} z_0 \times (p_E^B \times p_0^B) & z_1 & z_2 \times (p_E^B \times p_2^B) \\ z_0 & 0 & z_2 \end{bmatrix}$$

With:

- $z_1 = R_1^B * z_0$
- $z_2 = R_2^b * z_1$

By cross-checking with the toolbox we see that the following result is correct, paying attention at the inverted linear and angular velocity shown in the toolbox.

$$J_G = \begin{pmatrix} -\sin(q_1) & (d_1 - d_3 \sin(q_3)) & 0 & -d_3 \cos(q_1) \cos(q_3) \\ \cos(q_1) & (d_1 - d_3 \sin(q_3)) & 0 & -d_3 \cos(q_3) \sin(q_1) \\ 0 & 1 & -d_3 \sin(q_3) \\ 0 & 0 & \sin(q_1) \\ 0 & 0 & -\cos(q_1) \\ 1 & 0 & 0 \end{pmatrix}$$

Figure 6: Geometric Jacobian after simplification

## 1.7 Analytical Jacobian

We obtain the analytical Jacobian using the ZYZ euler angles T matrix:

$$J_A = T(\Phi)^{-1} J_G$$

with

$$R = \begin{pmatrix} 0 & -\sin(\phi) & \cos(\phi)\sin(\theta) \\ 0 & \cos(\phi) & \sin(\phi)\sin(\theta) \\ 1 & 0 & \cos(\theta) \end{pmatrix} \qquad T(\Phi) = \begin{pmatrix} I_3 & 0 \\ 0 & R \end{pmatrix}$$

obtaining:

$$J_A = \begin{pmatrix} -\sin(q_1) & (d_1 - d_3 \sin(q_3)) & 0 & -d_3 \cos(q_1) \cos(q_3) \\ \cos(q_1) & (d_1 - d_3 \sin(q_3)) & 0 & -d_3 \cos(q_3) \sin(q_1) \\ 0 & 1 & -d_3 \sin(q_3) \\ 1 & 0 & \frac{\sin(\phi - q_1) \cos(\theta)}{\sin(\theta)} \\ 0 & 0 & -\cos(\phi - q_1) \\ 0 & 0 & -\frac{\sin(\phi - q_1)}{\sin(\theta)} \end{pmatrix}$$

Figure 8: Analytical Jacobian after simplification

#### 2.1 Task

Compute the Kinetic and Potential energy

## 2.2 Kinetic energy

I've assumed homogeneus density for every link, and calculated the mass based on:

$$m = V * \rho$$

obtaining the following masses:

$$V_1 = 3.5186[kg]$$
  $V_2 = 2.16[kg]$   $V_3 = 2.41[kg]$ 

It'll follow the vectors which represent the position of the center of mass of each link with respect to it's frame:

$$p_{l1} = \begin{pmatrix} -\frac{d1}{2} \\ 0 \\ 0 \end{pmatrix} \quad p_{l12} = \begin{pmatrix} 0 \\ -\frac{d2}{2} \\ 0 \end{pmatrix} \quad p_{l2} = \begin{pmatrix} -\frac{d3}{2} \\ 0 \\ 0 \end{pmatrix}$$

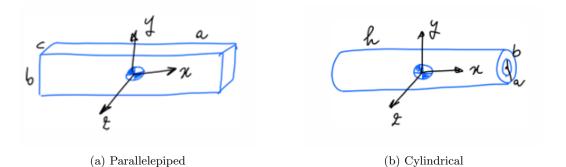

We then calculate then inertia matrices (w.r.t. CoM). In the case of a parallelepiped link we use:

$$I_C = \begin{pmatrix} \frac{1}{12}m(b^2 + c^2) & 0 & 0\\ 0 & \frac{1}{12}m(a^2 + c^2) & 0\\ 0 & 0 & \frac{1}{12}m(a^2 + b^2) \end{pmatrix}$$

In the case of a cylindrical link we use:

$$I_C = \begin{pmatrix} \frac{1}{2}m(a^2 + b^2) & 0 & 0\\ 0 & \frac{1}{2}m(3(a^2 + b^2)^2 + h^2) & 0\\ 0 & 0 & \frac{1}{2}m(3(a^2 + b^2)^2 + h^2) \end{pmatrix}$$

Following these:

We then obtain the inertia I of every link as:

$$I = I_c + m(r^T r I_{3x3} - r r^T)$$

where

- m = mass of the link
- $I_{3x3} = identity matrix$
- $\mathbf{r} = \text{distance of the } CoM_i \text{ w.r.t frame } \Sigma_i$

We now compute the Partial Jacobians, knowing that

- $p_{j-1}$  = position vector of the origin of Frame
- $z_{j-1} =$  the unit vector axis z of Frame  $\Sigma_{j-1}$  w.r.t  $\Sigma_0$

The columns of the Jacobian are:

$$J_{P_{j}}^{l_{i}} = \begin{cases} z_{j-1} & \text{prismatic joint} \\ z_{j-1} \times (p_{l_{i}} - p_{j-1}) & \text{revolute joint} \end{cases} \quad J_{O_{j}}^{l_{i}} = \begin{cases} 0 & \text{prismatic joint} \\ z_{j-1} & \text{revolute joint} \end{cases}$$

Finally we can compute the inertia matrix B(q):

$$B(q) = \sum_{i=1}^{n} (m_{li} J_P^{l_i}^T J_P^{l_i} + J_O^{l_i}^T R_i I_{l_i}^i R_i^T J_O^{l_i})$$

obtaining the following:

$$B(q) = \begin{pmatrix} 6.33 d_1^2 - 2.41 d_1 d_3 \sin(q_3) + 1.21 d_3^2 \sin(q_3)^2 + 0.069 \sin(q_3)^2 + 0.232 & 0 & 0 \\ 0 & 4.57 & -1.21 d_3 \sin(q_3) \\ 0 & -1.21 d_3 \sin(q_3) & 1.21 d_3^2 + 0.0695 \end{pmatrix}$$

And finally the total Kinetic Energy:

$$T(q,\dot{q}) = \frac{1}{2}\dot{q}^T B(q)\dot{q}$$

the result can be found in the code given its excessive length.

#### 2.3 Potential Energy

We can calculate the potential energy by adding all the single links contributions to each other, where every single contribution is expressed as:

$$U_{l_i} = -m_{l_i} g_0^T p_{l_i}$$

resulting in:

$$U = -34.3 * d_2 - 44.9 * q_2 - 11.8 * d_3 * cos(q_3)$$

#### 3.1 Task

Compute the equation of motion following the Lagrangian formulation.

#### 3.2 B matrix

The computation for the B matrix can be found in the previous assignment.

$$B(q) = \begin{pmatrix} 6.33 d_1^2 - 2.41 d_1 d_3 \sin(q_3) + 1.21 d_3^2 \sin(q_3)^2 + 0.069 \sin(q_3)^2 + 0.232 & 0 & 0 \\ 0 & 4.57 & -1.21 d_3 \sin(q_3) \\ 0 & -1.21 d_3 \sin(q_3) & 1.21 d_3^2 + 0.0695 \end{pmatrix}$$

#### 3.3 C matrix

We can find the C matrix by:

$$C_i(q,\dot{q}) = \sum_{j=1}^n \sum_{k=1}^n \frac{1}{2} \left( \frac{\delta b_{ij}}{\delta q_k} + \frac{\delta b_{ik}}{\delta q_j} + \frac{\delta b_{jk}}{\delta q_i} \right) \dot{q_k}$$

by summing all the contributions we obtain the following matrix:

$$C(q,\dot{q}) = \begin{pmatrix} \operatorname{dq}_3 \ \left( 0.603 \sin(2.0 \, q_3) \, d_3^{\, 2} - 1.21 \, d_1 \, \cos(q_3) \, d_3 + 0.0345 \sin(2.0 \, q_3) \right) & 0 & \operatorname{dq}_1 \ \left( 0.603 \sin(2.0 \, q_3) \, d_3^{\, 2} \\ & -1.21 \, d_1 \, \cos(q_3) \, d_3 + 0.0345 \sin(2.0 \, q_3) \right) \\ 0 & 0 & -1.21 \, d_3 \, \operatorname{dq}_3 \, \cos(q_3) \\ -1.0 \, \operatorname{dq}_1 \ \left( 0.603 \sin(2.0 \, q_3) \, d_3^{\, 2} - 1.21 \, d_1 \, \cos(q_3) \, d_3 + 0.0345 \sin(2.0 \, q_3) \right) & 0 & 0 \end{pmatrix}$$

#### 3.4 G matrix

We can find the g matrix by:

$$g(q) = -\sum_{i=1}^{n} m_{l_i} g_0^T \frac{\delta p_{l_i}}{\delta g_i}$$

obtaining:

$$g(q) = \begin{pmatrix} 0\\ 45.0\\ -12.0 d_3 \sin(q_3) \end{pmatrix}$$

#### 3.5 Equation of motion

We can finally find the equation of motion by:

$$\tau = B(q)\ddot{q} + C(q, \dot{q})\dot{q} + g(q)$$

#### 4.1 Task

Compute the RNE formulation

#### 4.2 Newton-Euler Formulation

We first execute the forward equations and then the backward equations:

```
1: /* Initial Conditions */
2: \omega_0, \beta_0 - g_0, \omega_0
3: \mathbf{for} I = 1 to n \mathbf{do}
4: Given current q_i, q_i, (i.e. \frac{g_i}{g_i}, \frac{g_i}{g_i}, or \mathbf{d}_i, \frac{g_i}{g_i}, or \frac{g_i}{g_i}, \frac{g_i}{g_i},
```

(a) Algorithm 1: forward equations

(b) Algorithm 2: backward equations

We can then get the needed matrices as follows:

• 
$$\tau_d = NE(q_d, \dot{q_d}, \ddot{q_d}, g_0)$$

• 
$$g(q) = NE(q, 0, 0, g_0)$$

• 
$$C(q, \dot{q}) = NE(q, \dot{q}, 0, 0)$$

• 
$$B_i(q) = NE(q, 0, e_i, 0)$$

#### 4.3 Results

It'll follow the comparison between lagrangian and RNE formulations given the following configuration:

• 
$$q = (pi/6, -0.15, -pi/3)$$

• 
$$\dot{q} = (9, 14, -7)$$

• 
$$\ddot{q} = (-4, 2.5, 5)$$

$$B_{lag} = \begin{pmatrix} 1.5 & 0 & 0 \\ 0 & 4.6 & 0.25 \\ 0 & 0.25 & 0.14 \end{pmatrix} \qquad B_{RNE} = \begin{pmatrix} 1.5 & 0 & 0 \\ 0 & 4.6 & 0.25 \\ 0 & 0.25 & 0.14 \end{pmatrix}$$

$$C_{lag}\dot{q} = \begin{pmatrix} 15.0 \\ -7.1 \\ 9.5 \end{pmatrix}$$
  $C_{RNE}\dot{q} = \begin{pmatrix} 15.0 \\ -7.1 \\ 9.5 \end{pmatrix}$ 

$$g_{lag} = \begin{pmatrix} 0 \\ 45.0 \\ 2.5 \end{pmatrix} \qquad g_{RNE} = \begin{pmatrix} 0 \\ 45.0 \\ 2.5 \end{pmatrix}$$

$$\tau_{lag} = \begin{pmatrix} 8.7 \\ 50.0 \\ 13.0 \end{pmatrix} \qquad \tau_{RNE} = \begin{pmatrix} 8.7 \\ 50.0 \\ 13.0 \end{pmatrix}$$

#### 5.1 Task

Compute the dynamic model in the operational space

# 5.2 Operational Space

The equations used for this assignment are the following:

- $B_A(x) = (J_a B^{-1} J_a^T)^{-1}$
- $C_A(x,\dot{x})\dot{x} = B_A J_A B^{-1} C \dot{q} B_A \dot{J}_A \dot{q}$
- $\bullet \ g_A(x) = B_A J_A B^{-1} g$
- $u_e = T_A^T(x)h$

## 6.1 Task

- Design the Joint Space PD control law with gravity compensation
- ullet What happens if g(q) is not taken into account?
- What happens if the gravity term is set constant and equal to  $g(q_d)$  within the control law?
- What happens if  $q_d$  is not constant (e.g.  $q_d(t) = \overline{q}_d + \Delta sin(\omega t)$ )?

## 6.2 Schemes

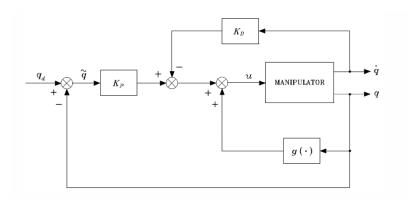

Figure 15: Joint Space PD control with gravity compensation block scheme

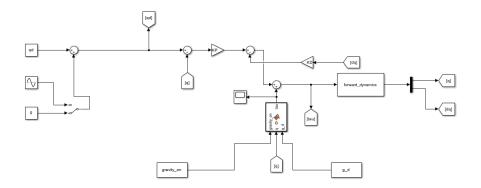

Figure 16: Simulink implementation of the Joint Space PD control with gravity compensation block scheme

I chose as starting position [0;0;0] and as the desired final position  $\left[\frac{\pi}{6};0.1;\frac{\pi}{3}\right]$ 

#### 6.3.1 Gravity compensation on

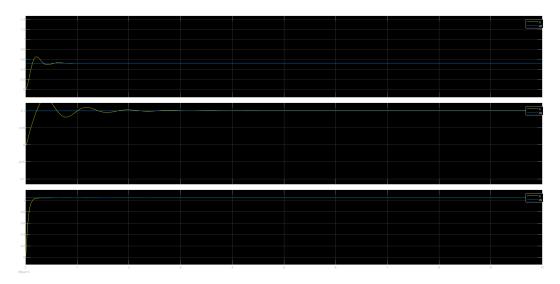

Figure 17: Results with gravity compensation active

As we can see we perfectly asymptotically reach the desired position in all the joints.

#### 6.3.2 Graivity compensation off

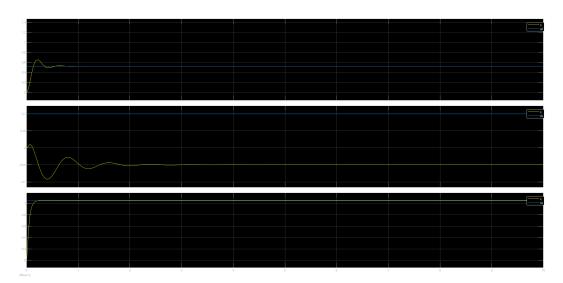

Figure 18: Results with gravity compensation not active

In this case we can see that the asymptotically result is not achieved for the second and third joint, which is what we expect since the gravity affects only those two and not the first one.

#### 6.3.3 Constant desired gravity compensation

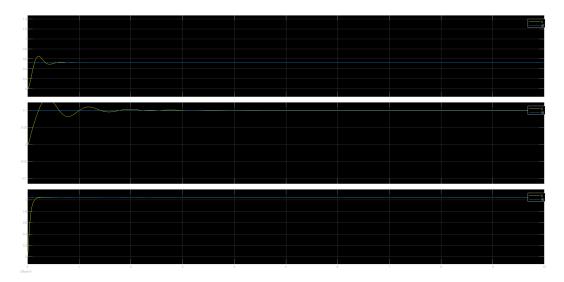

Figure 19: Results with constant gravity compensation

Here we applied a constant gravity compensation based on the final position and not on the current one, since the gravity term guarantees the final position it is expected, as we find in the plot, that at the end the desired position is perfectly achieved

### 6.3.4 Not constant desired position

In the case of a not constant desired position we obtain the following result:

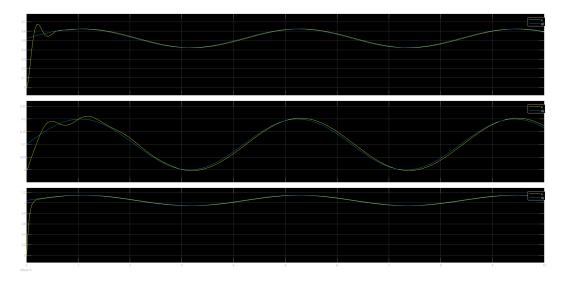

Figure 20: Results with gravity compensation active but not a constant desired position

#### 7.1 Task

- Design the Joint Space Inverse Dynamics Controls law
- Check that in the nominal case the dynamic behaviour behaviour is equivalent to the one of a set of stabilized double integrators
- Check the behaviour of the control law when the  $\hat{B}, \hat{C}, \hat{g}$  used within the controller are different than the "true ones" B,C,g
- What happens to the torque values when the setting time of the equivalent second order systems is chosen very small

#### 7.2 Schemes

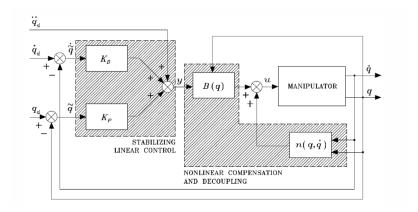

Figure 21: Joint Space Inverse Dynamics Control law block scheme

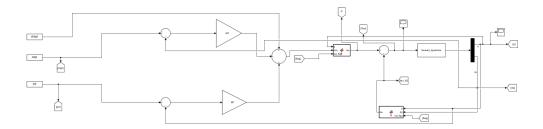

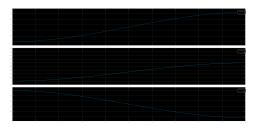

Figure 22: Simulink implementation of the Joint Space Inverse Dynamics Control law block scheme

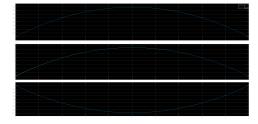

I chose as starting position [0;0;0] and as the desired final position  $\left[\frac{\pi}{6};0.1;-\frac{\pi}{3}\right]$ 

#### 7.3.1 Correct model

Here we can see that by using the correct matrices B,C,g we can obtain a perfect match between the desired and actual position.

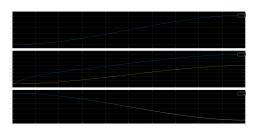

(a) positions plot for correct matrices

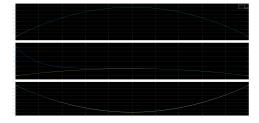

(b) velocities plot for correct matrices

#### 7.3.2 Wrong model

Here we can see that by using the altered matrices  $\hat{B}, \hat{C}, \hat{g}$  we lose the overlap, and as expected the second and third joint don't respect the final desired position as the g matrix which is responsible for that is not the correct one.

(a) positions plot for altered matrices

(b) velocities plot for altered matrices

#### 7.4 Small execution time

If we set our desired time to reach the final position small, in this case is one second, we can observe some instantaneous peaks in the torques given to the joints (especially the second one in this case).

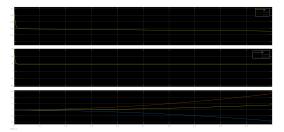

Figure 25: Torques for t=1

#### 8.1 Task

Implement in Simulink the Adaptive Control law for a 1-DoF link under gravity. Choose the dynamic parameters and their initial estimates, and set the desired trajectory as

- $q_d(t) = Asin(\omega t)$
- $\ddot{q}_d(t)$  = periodic square wave +A

## 8.2 Schemes

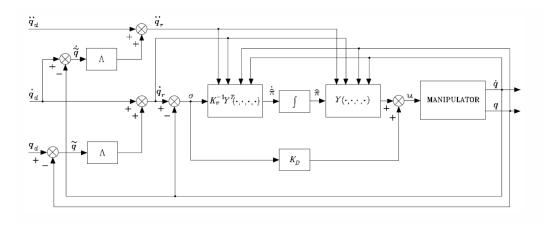

Figure 26: Joint Space Adaptive Control law block scheme

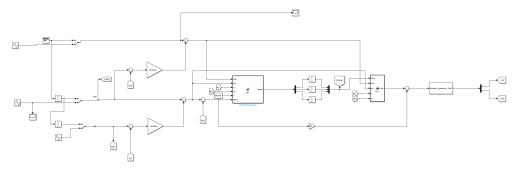

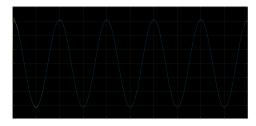

Figure 27: Simulink implementation of Joint Space Adaptive Control law block scheme

#### 8.3.1 Sinusoidal

For the sinusoidal position we obtain a perfect match in the desired position:

(a) positions plot sinusoidal input

(b) velocities plot for sinusoidal input

with the following estimations:

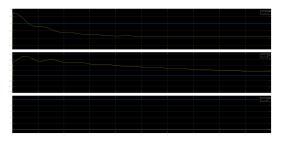

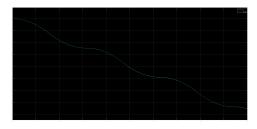

Figure 29: I,F,G and the estimated ones

#### 8.3.2 Square wave

For the square wave acceleration we obtain a perfect match in the desired position:

(a) positions plot square wave input

(b) velocities plot for square wave input

with the following estimations:

Figure 31: I,F,G and the estimated ones

## 9.1 Task

Design the Operational Space PD control law with gravity compensation

# 9.2 Schemes

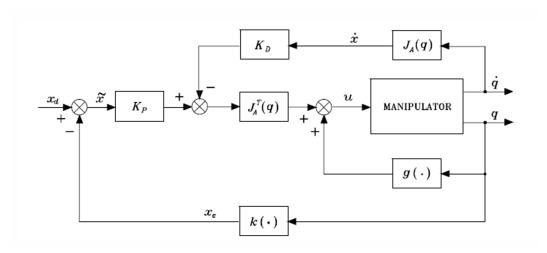

Figure 32: Operational Space PD control with gravity compensation block scheme

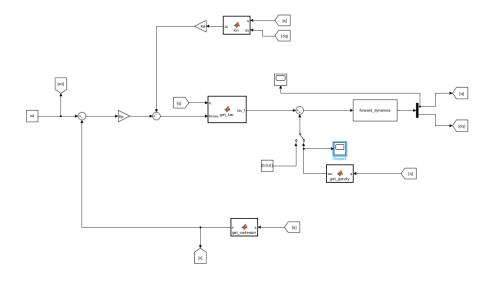

Figure 33: Simulink implementation of Operational Space PD control with gravity compensation block scheme

It was chosen as starting joint configuration [0;0;0] and as final  $[\frac{pi}{3};0.4;-\frac{pi}{2}]$  then converted into cartesian space.

## 9.3.1 Gravity on

Here we can see that the desired position in the cartesian space is perfectly reached in all x,y and z.

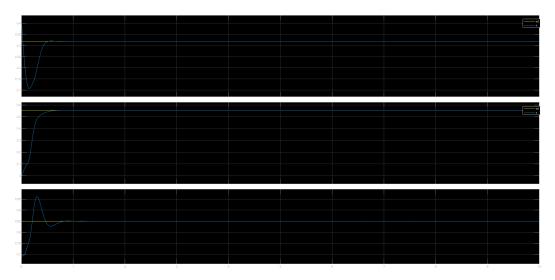

Figure 34: Position plot with gravity compensation active

## 9.3.2 Gravity off

Here we can see that the desired position in the cartesian space is not reached, especially in z, but this is expected given that the second joint which affects the z position is not applying the required torque to compensate the gravity effect.

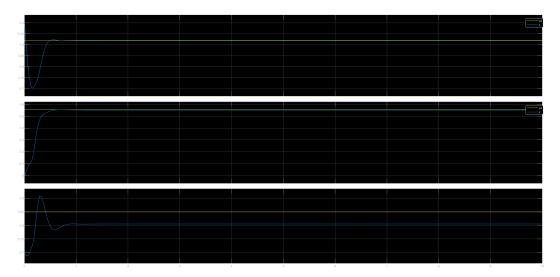

Figure 35: Position plot with gravity compensation turned off

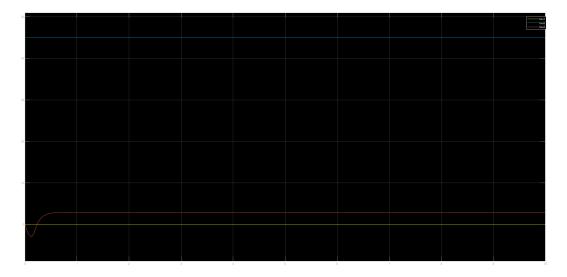

Figure 36: Tau required for all joints

## 10.1 Task

Design the Operational Space Inverse Dynamics Control law

# 10.2 Schemes

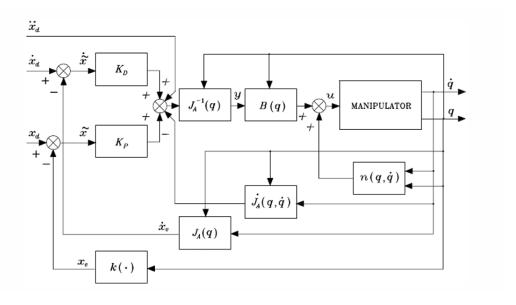

Figure 37: Operational Space Inverse Dynamics Control law block scheme

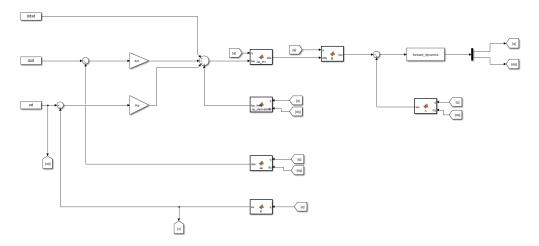

Figure 38: Simulink implementation of Operational Space Inverse Dynamics Control law block scheme

A cubical trajectory was calculated in the joint space from [0;0;0] to  $\left[\frac{-\pi}{3};0.3;\frac{\pi}{2}\right]$  and then converted into the cartesian space. As we can see in the following images we obtain as expected a perfect tracking of the desired trajectery in the position and orientation of the end effector

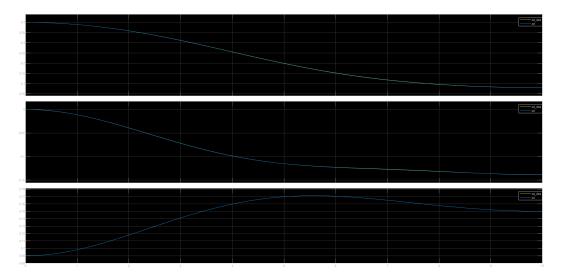

Figure 39: EE position

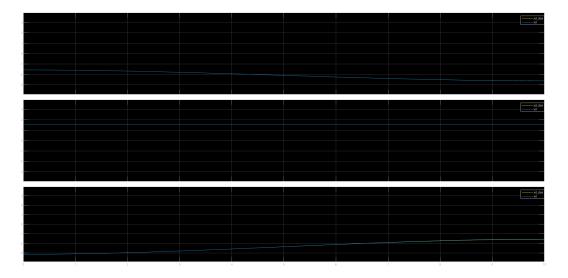

Figure 40: EE orientation

#### 11.1 Task

Study the compliance control. Simulate the two "extreme" cases when the end-effector is interacting with the environment(considered as a planar surface)

## 11.2 Theory

We report the control law for the compliance control:

$$\begin{split} \tau &= g(q) + J_{A_d}^T(q, \tilde{x})(K_P \tilde{x} - K_D(q, \tilde{x})\dot{q}) \\ \tilde{x} &= x_d - x_e = - \begin{bmatrix} o_{d,e}^d \\ \phi_{d,e} \end{bmatrix} \\ J_{A_d} &= T_a^{-1}(\phi_{d,e}) \begin{bmatrix} R_d^T & 0 \\ 0 & R_d^T \end{bmatrix} \end{split}$$

The planar environment was designed along the z direction considering the configuration of my robot. The external wrench was computed on z by calculating the displacement between environmental rest position and the EE position:

$$h_e = Kx_{r,e}$$

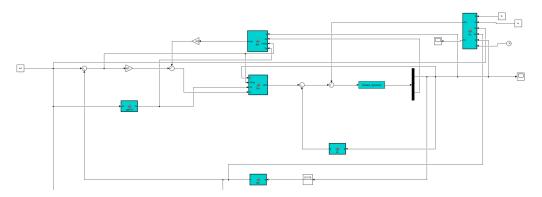

Figure 41: Simulink implementation of Compliance control block scheme

#### 11.3.1 Case K>>KP

In this case the environment stops completely the end effector, in this case we set  $K_P = 50$  and K = 500.

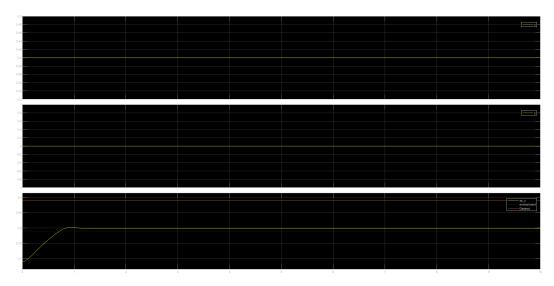

Figure 42: Environment >> Robot

#### 11.3.2 Case K=KP

In this case the environment can't completely stop the robot, and since K is equal to  $K_p$  (50) the EE stops at halfway between the desired position and the rest position of the environment

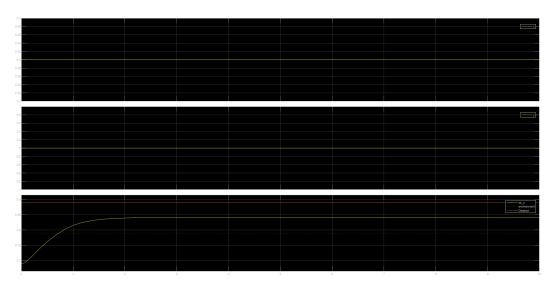

Figure 43: Environment = Robot

# $11.3.3\quad Case\ K{<<}KP$

In this we set K=1 and  $K_p=50$ . We can see that the environment can't stop the robot as it reaches its desired position

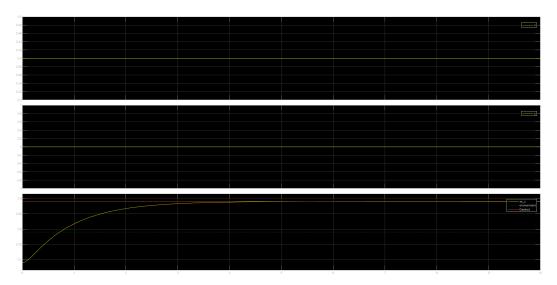

Figure 44: Environment << Robot

#### 12.1 Task

Implement the admittance control in the operational space

## 12.2 Schemes

We report the admittance general scheme:

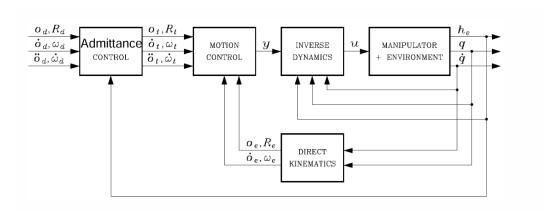

Figure 45: Admittance control

and my Simulink implementation:

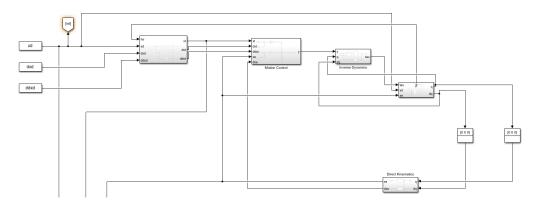

Figure 46: Simulink implementation of the admittance control

In this case the Admittance control block feeds a new trajectory to the motion control based on the desired one modified accordingly to the contact force with the environment.

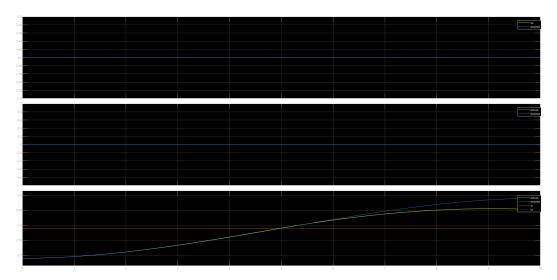

Figure 47: Position of EE with environment,  $K_p=50$  and K=10

In this plot we can see that on the z axis the trajectory follows the desired until the collision with the environment and then follows  $x_t$ .

#### 13.1 Task

Implement the Force Control with inner position Loop.  $(C_F(s)=K_F \text{ and } C_F(s)=K_F+\frac{1}{s}K_I)$ 

## 13.2 Theory

We consider the following equations for the system:

$$\begin{cases} B(q)\ddot{q} + C(q,\dot{q})\dot{q} = \tau - J^{T}(q)h_{e} \\ \tau = B(q)y + n(q,\dot{q}) + J^{T}(q)h_{e} \\ y = J^{-1}(q)M_{d}^{-1}(-K_{D}\dot{x_{e}} + K_{p}(x_{F} - x_{e}) - M_{d}\dot{J}(q,\dot{q})\dot{q}) \end{cases}$$

# **13.3.1** $K_I$ and $K_F$

In this case the  $C_F$  is modelled as a PI controller  $(K_F + K_I \frac{1}{s})$ , in particular  $K_I = K_F = 5$ . In this case we reach the zero-steady error at the position  $Kx_e = Kx_r + f_d$ 

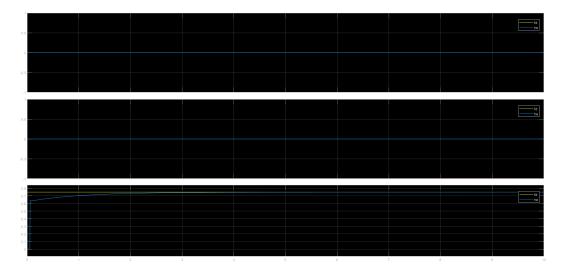

Figure 48: Force of EE and environment contact,  $\!K_F=5$  and K=5

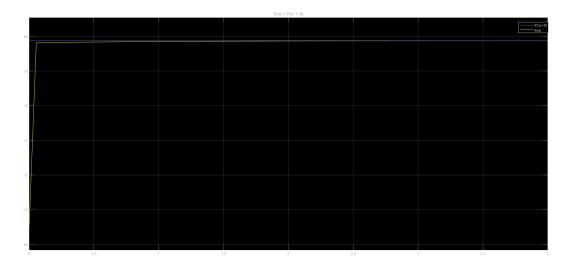

Figure 49:  $Kx_e = Kx_r + f_d$ 

# 13.3.2 $K_F$

In this case the  $C_F$  is modelled as a P controller  $(K_F)$ , in particular  $K_F = 5$ . In this case we do not reach the zero-steady error.

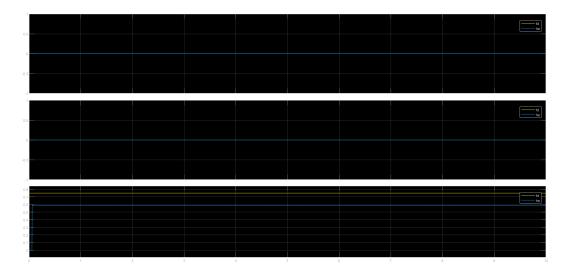

Figure 50: Force of EE and environment contact,  $\!K_F=5$  and K=5

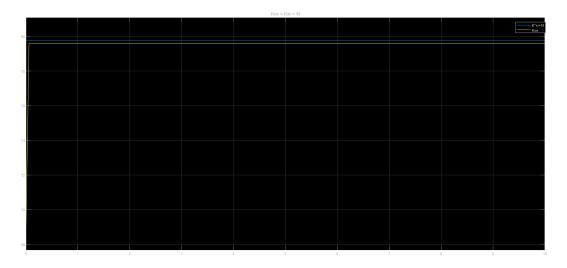

Figure 51:  $Kx_e$  and  $Kx_r + f_d$ 

## 14.1 Task

Implement the Parallel Force/Position Control.  $(C_F(s) = K_F \text{ and } C_F(s) = K_F + \frac{1}{s}K_I)$ 

We consider the following equations for the system:

$$\begin{cases} B(q)\ddot{q} + C(q,\dot{q})\dot{q} = \tau - J^{T}(q)h_{e} \\ \tau = B(q)y + n(q,\dot{q}) + J^{T}(q)h_{e} \\ y = J^{-1}(q)M_{d}^{-1}(-K_{D}\dot{x_{e}} + K_{p}(x_{F} - x_{e} + xd) - M_{d}\dot{J}_{A}(q,\dot{q})\dot{q}) \end{cases}$$

In the following we can see that the x and y axis follow the position control whilst the z axis follows the force control.

## **14.3.1** $K_I$ and $K_F$

In this case the  $C_F$  is modelled as a PI controller  $(K_F + K_I \frac{1}{s})$ , in particular  $K_I = K_F = 5$ . In this case we reach the zero-steady error as we can see in the force graphs for the z axis.

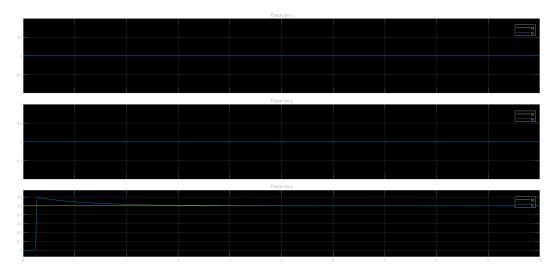

Figure 52: Force of EE and environment contact,  $\!K_F=5$  and  $K_I=5$ 

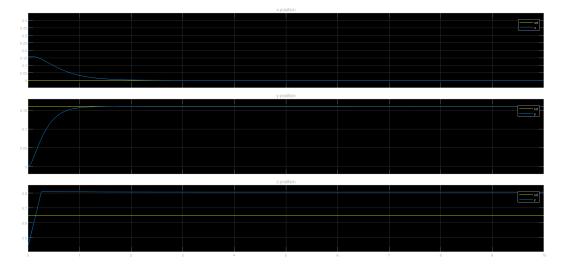

Figure 53: Position of EE with  $K_F=5$  and  $K_I=5$ 

# 14.3.2 $K_F$

In this case the  $C_F$  is modelled as a P controller  $(K_F)$ , in particular  $K_F = 5$ . In this case we do not reach the zero-steady error.

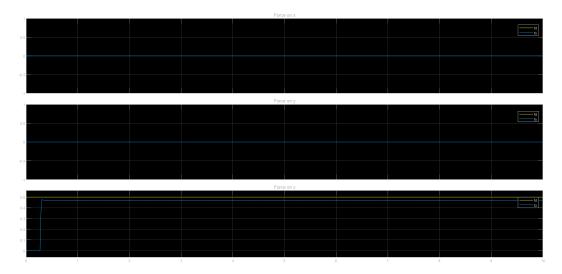

Figure 54: Force of EE with  $K_F = 5$ 

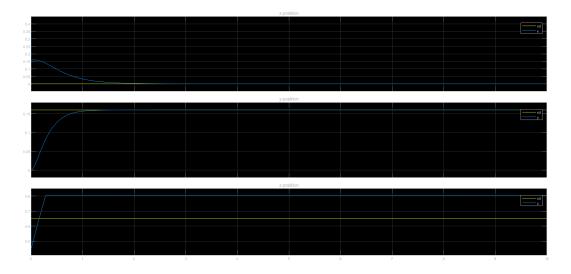

Figure 55: Position of EE with  $K_F=5$
